*Brief Report*

2

**3 Affective feelings and perceived exertion during a 10-km time trial and head-to-**  
**4 head running race**

5

**6 Abstract**

**7 Purpose:**

8 Our aim was to verify the affective feelings (AF) and rating of perceived exertion (RPE)  
9 responses during a 10-km competitive head-to-head (HTH) and compare it to a time-  
10 trial (TT) running race.

**11 Methods:**

12 Fourteen male runners completed 2 x 10-km runs (TT and HTH) on different days.  
13 Speed, RPE and AF were measured every 400-m. For pacing analysis races were  
14 divided into four stages: I) first 400 m (F400); II) 401m to 5000m (M1); III) 5001m and  
15 9600m (M2) and; **IV**) the last 400m (final sprint [FS]).

**16 Results:**

17 **Improvement of performance was observed** (39:32 ± 02:41 min:s vs 40:28 ± 02:55  
18 min:s; p = 0.03; ES = - 0.32) in HTH compared to TT. There were **not** differences in  
19 **either** pacing strategy or RPE between conditions. **AF were** higher during the HTH,  
20 **being different** in M2 when compared to TT (2.09 ± 1.81 vs 0.22 ± 2.25; p = 0.02; ES =  
21 0.84).

**22 Conclusion:**

23 **AF** are directly influenced by the presence of opponents during a HTH race and a more  
24 positive AF could be involved in the dissociation between RPE and running speed and  
25 consequently, the overall race performance.

26

## 51 Introduction

52 Pacing strategy has been defined as the athlete's adjustment of the exercise  
53 intensity during a race<sup>1</sup> and seems to be controlled by a complex intuitive/deliberate  
54 decision-making process<sup>2</sup> influenced by physiological, psychological, environmental  
55 and tactical factors<sup>2,3</sup>.

56 The rating of perceived exertion (RPE) has been considered an important factor  
57 in pacing adjustments, where athletes control the exercise intensity to reach the highest  
58 values of RPE at the end of the race<sup>3-5</sup>. However, during a race athletes experience  
59 multiple perceptual responses<sup>3</sup> and assuming that RPE is the only factor for explaining  
60 pacing strategy is an oversimplification of a complex process. Therefore, other  
61 psychological factors such as the construction of affect have an important role in  
62 exercise intensity<sup>3,5</sup>.

63 Affective feelings (AF) of pleasure–displeasure involve interpretations of mood  
64 and emotions experienced by the individual in a given situation<sup>6</sup>. While RPE represents  
65 how athletes feel, AF represent what they feel<sup>6</sup>. In addition, AF will be generated by the  
66 athlete's perception of performance in relation to their goals and expectations<sup>3</sup>.

67 AF-pacing relationship has been observed during time-trial races<sup>5,7</sup> where the  
68 goal is to achieve the best time possible or in a well-controlled laboratory and against  
69 virtual opponents<sup>8</sup> where the effects of external influences as a position in the pack,  
70 environmental factor and opponents behavior are less predominant than a real head-to-  
71 head race<sup>9</sup>. In addition, AF-pacing relationship could be different when incorporating  
72 human-environment interactions. Casado et al.<sup>10</sup> verified AF in a real human-  
73 environment interaction during athletes' training routine and observed that in session  
74 performed collectively the metabolic strain and RPE were lower and AF were higher  
75 compared to a session performed individually. However, this study had a collaborative  
76 rather than the competitive nature, which can have an important impact on the results.  
77 Therefore, the aim of the study was to verify AF and RPE responses during a 10-km  
78 competitive head-to-head running race situation and compare them to time-trial running.  
79

## 80 Methods

### 81 *Participants*

82 Fourteen trained male runners ( $33.3 \pm 6.1$  yrs,  $69.5 \pm 9.1$  kg,  $172 \pm 8$  cm,  $56.7 \pm$   
83  $6.2$  ml·kg<sup>-1</sup>·min<sup>-1</sup>), with at least 2 years' experience and able to run 10 km in less than 45  
84 minutes participated in the study. The study was approved by the local Ethics  
85 Committee according to the Declaration of Helsinki and each volunteer signed a written  
86 informed-consent form after receiving an explanation of the experimental procedures,  
87 possible risks, and benefits.  
88

### 89 *Experimental procedures*

90 After familiarization sessions participants completed three experimental sessions  
91 separated by at least 144 hours. During the first session, all of them performed an  
92 incremental maximal exercise test to assess their maximal oxygen uptake (**VO<sub>2</sub>max**;  
93 Quark b<sup>2</sup>, Cosmed, Rome, Italy). The second and third experimental sessions were  
94 performed in a random order but at same time of the day ( $\pm 2$ h). The runners performed  
95 2 x 10-km runs, one of them being a time-trial (TT) and the other a head-to-head (HTH)  
96 10-km run. The TT was performed with one athlete at a time on the track. In the HTH  
97 all of the athletes (n=14) were positioned on the same start line. The running time was  
98 determined with a manual stopwatch (**Hs-70w-1df, Casio, Tokyo, Japan**) and prior to  
99 running participants were always instructed to attempt to achieve their best performance  
100 possible (best time or best position possible).

101 They were free to choose their own pacing strategy and constantly updated on  
102 the distance covered throughout the runs. Average speed, RPE (Borg's 6-20 Scale) and  
103 affective feelings (AF; feelings scale) were collected at every lap (400-m). Small scales  
104 were fixed to athlete's forearms to allow consultation when necessary. During HTH  
105 sessions each athlete was assigned to a researcher who was responsible for collecting  
106 the information at each lap. In all sessions participants were instructed to refrain from  
107 any exhaustive or unaccustomed exercise for at least 48h and they were instructed to  
108 avoid the consumption of caffeine or any other stimulants during the 24h period prior to  
109 the experimental sessions.

110

### 111 **Statistical analysis**

112 All values are presented as means  $\pm$  standard deviation (SD). A paired t-test was  
113 used to compare race time between conditions. For the analysis of pacing, RPE, and AF,  
114 the 10-km race was divided into four stages: I) first 400 m (F400); II) between 401 m  
115 and 5000 m (M1); III) between 5001 m and 9600 m (M2) and; **IV**) the last 400m (final  
116 sprint [FS]). Average speed, RPE and AF were analyzed by a two-way repeated  
117 measures ANOVA followed by a post hoc of Tukey. The effect size (ES) was calculated  
118 and interpreted by using values of 0.2, 0.6, 1.2, 2.0 and 4.0 of the variation as  
119 thresholds for small, moderate, large, very large, and extremely large<sup>11</sup>. Statistical  
120 significance level was set at the  $p \leq 0.05$ . All statistical analyses were conducted using  
121 the SAS<sup>®</sup> statistical package (version 9.3, Cary, USA).

122

### 123 **Results**

124 From the 14 participants who started the race, eleven runners completed the  
125 HTH race and their data was used for the statistical analysis.

126 A small but significant improvement of 2.3% was observed in performance  
127 when HTH was compared to TT (39:32  $\pm$  02:41 min:s vs 40:28  $\pm$  02:55 min:s;  $p = 0.03$ ;  
128 ES = - 0.32).

129 In both conditions athletes performed a classical "U-shaped" pacing strategy<sup>1</sup>  
130 without differences in relative average speed between conditions in any race stage  
131 (Figure 1A). In the same way, there were no differences between conditions in RPE,  
132 which increased linearly during both races (Figure 1B). During the TT, AF decreased  
133 progressively during the race reaching the lowest values in FS (0.16  $\pm$  3.12). On the  
134 other hand, AF were higher during HTH (Figure 1C), with a significant difference and  
135 moderate effect size between conditions observed only in M2 (HTH = 2.09  $\pm$  1.81 vs  
136 TT = 0.22  $\pm$  2.25;  $p = 0.02$ ; ES = 0.84).

137

138 *Insert FIGURE 1*

139

140 A great individual variation in relative average speed was observed when TT  
141 and HTH were compared. RPE seems to have been less influenced by the presence of  
142 opponents while a great individual variation was observed in AF responses throughout  
143 the race when comparing TT and HTH (FIGURE 2).

144

145 *Insert FIGURE 2*

146

### 147 **Discussion**

148 These findings show that while RPE was slightly affected by the opponent's  
149 presence, AF were higher during HTH. RPE increased progressively throughout the 10-

150 km in both conditions, which shows that athletes adjust the effort according to the  
151 distance to be covered and its pattern hardly changes<sup>4,5</sup>.

152 Performance was improved in HTH condition, which is not novel<sup>9</sup>, while the  
153 pacing strategy did not change. The better performance in HTH can be attributed to  
154 small increases in average speed during the race, which suggests a possible dissociation  
155 between RPE and running speed, at least in part, explained by differences in AF<sup>3,5</sup>. In  
156 fact, positive AF has been associated with higher speeds when compared to negative  
157 ones<sup>3,5,7</sup>.

158 Since AF are related to physiological stress<sup>5</sup>, results from HTH may have been  
159 affected by drafting<sup>12</sup> and the effects of running in group<sup>10</sup>. Casado et al.<sup>10</sup> reported  
160 lower RPE and blood lactate during their group training session. However, the effects of  
161 drafting on energy-saving are more noticeable at higher speeds than those observed in  
162 the present study<sup>10,12</sup>. Additionally, Casado et al.<sup>10</sup> study was performed at a more  
163 collaborative than competitive environment, which alters the decision-making process  
164 and the relationship of AF against goals and expectations<sup>3</sup>

165 During a TT, the goal is simpler (to achieve the best time possible) and success  
166 is self-referenced<sup>7</sup>. The attentional focus is internal and AF can be associated to exercise  
167 intensity and RPE, which explains why AF decrease whereas RPE increases in TT.  
168 Conversely, in HTH goal setting is crossing the finish line ahead of the opponents and  
169 the athlete–environment interaction changes the attentional focus from internal to  
170 external aspects<sup>13</sup>. This should be deduced in the data of the three participants who  
171 dropped out of HTH. The moment they dropped out of the HTH they reported similar  
172 RPE to that of the TT (athlete 1 = 16 vs 17; athlete 2 = 15 vs 14; athlete 3 = 8 vs 7), but  
173 they experienced more negative AF (athlete 1 = -5 vs 0; athlete 2 = -5 vs -2; athlete 3 =  
174 -5 vs -2) which could be associated to lower motivation and goal expectation.  
175 Considering the similarity between RPE and the reduced AF, it is conceivable that these  
176 participants dropped out as a consequence of negative feelings, and not due to a  
177 physiological failure, in a decision-making based on expectations, risks and rewards.  
178 However, this was an observational study and we did not attempt to directly manipulate  
179 AF. Future studies should be developed with AF as a variable of interest to provide a  
180 better understanding of its influence on decision-making and pacing strategy during  
181 middle/long distance races.

### 182 **183 Practical Applications**

184 Maintaining high levels of AF seems to influence performance positively in long-  
185 distance running races. Therefore, strategies related to goal setting should be developed  
186 with athletes to change their attention focus and expectations of success during races.

### 187 **188 Conclusions**

189 AF are directly influenced by the presence of opponents during a HTH race and a more  
190 positive AF would be involved in the dissociation between RPE and running speed and  
191 consequently, the overall race performance.

### 192 **193 Acknowledgments**

194 The authors thank the participants of the study and all of the researches involved in the  
195 data collection

### 196 **197 Declaration of Conflicting Interests**

198 The author(s) declared no potential conflicts of interest with respect to the research,  
199 authorship, and/or publication of this article.
